The fringe order number can be found by counting the number of fringes: $m = \# \text{fringes}$ (23.4) For small angles measured in radians, the small angle approximation (refer to Experiment 11) is useful: $\sin \theta \approx \tan \theta = y/L$ (23.5) Using substitution, Eq. 23.3 and Eq. 23.5 are solved for θ , in terms of quantities that can be

Optics with diameters less than 3.00mm, such as micro-lenses or micro-prisms, are typically not beveled due to the likelihood of creating edge chips in the process. It is important to note that for small radii of curvature, for example, lenses where the diameter is $\geq 0.85 \times$ radius of curvature, no bevel is needed due to the large angle between the surface and edge of the lens.

Fringe patterns on the DMD were projected at the sample plane passing through a demagnifying imaging system including a collimating lens and a $100\times$ oil objective. The higher orders of spatial frequencies of the binary fringe are naturally blocked by the imaging system thereby leading to a near-sinusoidal striped light field at the sample plane.
